Something in the air

for chamber ensemble

To celebrate the 50th anniversary of the *Clean Air Act*:
a musical map of the decline of six air pollutants,
as well as the congressional voting records
that successfully enacted and amended this law.

Eric Banks

Commissioned by the *Verge Ensemble* in January and February 2014,
to be premiered on 6 April 2014 in the concert, *Sonic ecologies*.

Email: eric@ericbanks.com Webpage: www.ericbanks.com

About this work

When Dan Visconti approached me about composing a work for the *Verge Ensemble*, I knew that I wanted to construct a musical map.
At first, we tossed around the idea of mapping the super-storm Hurricane Sandy, but I decided to focus a more positive event.
In order to acknowledge that the United States Congress was once proactive and responsible for good environmental policy,
I wanted to create a piece that would tell the success story of the Clean Air Act, which was voted into law 50 years ago.

This piece is a musical map. It renders into sound the declining densities of six different air pollutants between 1980
(when the EPA began to measure these pollutants) and 2010. Each pollutant is represented by a different instrument in the ensemble:
Carbon monoxide (CO) by the flute, Ground-level ozone (O_3) by the violin, Sulfur dioxide (SO_2) by the clarinet, Nitrogen dioxide (NO_2)
by the cello, Lead (Pb) by the vibraphone, and two different sizes of Particulate Matter (PM 2.5 and 10) by the marimba.

Every year, each of the six pollutants is recorded as a **MEAN** (in parts per billion, or PPB) or in micrograms per cubic meter.
Each yearly mean is represented as a reciting tone in the melodies of the piece, played on weaker beats or partials of the beat.
Each pollutant also has a standard **DEVIATION** (up to the 90th above the mean and down to the 10th percentile below the mean).
These deviations are represented by the range of pitches that wander above and below the reciting-tone mean for each year.

There are 31 years of statistics encompassed by this score, and each year is a 6-bar section (or stave) in a single key.
With each ensuing year, there is a slight modulation, to the next (sharper) key in the circle of fifths.

Here is a table of the data that I collected from the EPA's website:

Pollutant		1980	1981	1982	1983	1984	1985	1986	1987	1988	1989	1990	1991	1992	1993	1994	1995	1996	1997	1998	1999	2000	2001	2002	2003	2004	2005	2006	2007	2008	2009	2010

Above, you can see the keys that are attached to each ensuing year (and 6-bar segment). You can also see the reciting tone (RT) of each year, as well as the high and low pitches (H and L) that wander above and below each reciting tone. Notice that PM 10 was not measured until 1990, and that PM 2.5 was not tracked until the year 2000. This is precisely why there is no marimba part for the first third of the piece.

This piece also tracks the congressional voting record for the Clean Air Act. These episodes occur during the gray VOTE stripes above. There were three votes for the Clean Air Act: the first in 1963 to enact the law, and two subsequent votes to amend it, in 1967 and 1990. I decided to represent these votes as a "rapid roll call" of staccato sixteenth-notes. Imagine if all 435 members of the House were to say "Yea" or "Nay" in quick, sixteenth-note succession, in alphabetical order by state, and in numerical order by district. Then, insert a single sixteenth-rest between each state's listing in the roll call. The endless string of 435 votes becomes a stuttering series of 484 sixteenth notes and rests, or 121 quarter-note beats. Divide this total by 6, and you will get about 20 beats (or, in 4/4 meter, about 5 measures of staccato "rapid roll call" for each the 6 gray VOTE episodes above.

Each vote in the "rapid roll call" is also represented by pitch. In each tetrachord, the highest pitch represents a Democratic "Yea," the second-highest a Republican "Yea," the second-lowest a Democratic "Nay," and the lowest a Republican "Nay" or silence. Remember that there were three votes (in 1963, 1967, and 1990). These three "rapid roll calls" are superimposed in each episode. The 1963 and 1967 "roll calls" are homophonic with each other. However, due to redistricting between 1967 and 1990, the rests that demarcate each new state in the list of the 1990 "roll call" fall differently than in the earlier votes. Each of these three "roll calls" is still 484 sixteenths in duration, and their superimposed episodes are marked *battibecchi* (or bickering) in the score. (These voting episodes are found at the rehearsal letters A, C, E, G, I, and K).

Wait; there's more! The melodies in this piece are meant to be recited or sung (*colloquiale* or *cantabile* in the score) because they are based on texts that describe each of the six pollutants (and coda that is a bit of a mission statement). These texts are adapted from the official website of the EPA:

Carbon monoxide is a colorless, odorless gas, emitted from combustion processes. Nationally, and particularly in urban areas, the majority of carbon monoxide emissions to ambient air come from mobile sources. Carbon monoxide can cause harmful health effects by reducing the delivery of oxygen to the tissues and the organs of the body. At extremely high levels, carbon monoxide can cause death.

Ground-level ozone is not emitted directly into the air, but is created by chemical reactions between oxides of nitrogen and volatile organic compounds in the presence of sunlight. Emissions from industrial facilities and electric utilities, motor vehicle exhaust, gasoline vapors, and chemical solvents are some of its major sources. Ground-level ozone can have harmful effects on sensitive vegetation, and adverse impacts on ecosystems, including: loss of species diversity, changes to habitat quality, and disruption of water and nutrient cycles.

Sulfur dioxide is one of a group of highly-reactive gasses known as "oxides of sulfur." The largest sources of sulfur dioxide emissions are from fossil-fuel combustion at power plants and other industrial facilities. Smaller sources of sulfur dioxide emissions include industrial processes, such as: extracting metal from ore, and the burning of high sulfur-containing fuels by locomotives, large ships, and off-road equipment. Sulfur dioxide is connected to a number of adverse effects on the human respiratory system.

Nitrogen dioxide is one of a group of highly-reactive gasses known as "oxides of nitrogen" or "nitrogen oxides." The National Ambient Air Quality Standard of the EPA uses nitrogen dioxide as the indicator for the larger group of nitrogen oxides in the air. Nitrogen dioxide forms quickly from emissions from cars, trucks, busses, power plants, and off-road equipment. In addition to contributing to the formation of ground-level ozone, and fine-particle pollution, nitrogen dioxide is connected to a number of adverse effects on the human respiratory system.

Lead is a metal that is found naturally in the environment as well as in manufactured products. The major sources of lead emissions have historically been from motor-vehicle fuels and industrial sources. As a result of regulatory efforts from the Environmental Protection Agency that removed lead from motor-vehicle gasoline, emissions of lead and levels of lead in the air have both dramatically declined in the transportation sector. Today, the highest levels of lead in air are usually found near lead smelters, and the major sources of lead emissions are ore and metals processing, and aircraft that operate on leaded aviation gasoline.

Particulate matter, also known as "particle pollution," is a complex mixture of extremely small particles and liquid droplets. Particle pollution is made up of a number of components, including acids, organic chemicals, metals, soil, and dust. The size of these particles is directly related to their potential for causing health problems. The Environmental Protection Agency groups particle pollution into two categories. "Inhalable coarse particles" are found near roadways and dusty industries. "Fine particles," such as those found in smoke and haze, can be directly emitted from sources such as forest fires, or can form when gasses from power plants and automobiles react in the air. These particles pass through the throat and nose and enter the lungs. Once inhaled, these particles can cause serious health effects.

In recent years, the EPA has acted to dramatically improve America's air quality by designing and developing national programs that, when fully implemented, will achieve significant reductions in air emissions. The benefits associated with a better quality of air will lead to improved health, longevity, and quality of life for all.

The texts of these 7 paragraphs create the rhythms found at the beginning of the piece, as well as at rehearsal letters B, D, F, H, J, and L.

In order for this map to be an accurate depiction of *relative* pollutant density, the ranges are particularly low. Also, it's important to remember that this is an actual *success* story for governmental regulation, and pollution levels *decrease* over the course of the piece. Therefore, please make room for the very low register of the flute, and understand why the smaller melodic ranges will "bumble along" toward the end of the piece. If the vibraphone and marimba lines cannot be performed simultaneously by the same player, I suggest playing both lines on the vibraphone, but using soft mallets for the written marimba part and hard mallets for the vibraphone part (however, never with tremolo).

Thank you to Dan and the entire *Verge Ensemble* for this opportunity!
I hope that you and your audience will enjoy this coming together
of science, nature, politics, history, and music.

Eric Banks

Something in the air

Commissioned by the *Verge Ensemble*
to be premiered on 6 April 2014
in the concert, *Sonic ecologies*
